The graph showing injury rates from fireworks in the UK in 1984 and 1998. In both charts, the highest proportion of injuries caused by open places, and the lowest was caused by children playing alone, 5% in 1984 and 11% in 1998.

However, the charts also show that between 1984 and 1998, the frequency of children playing alone increased from 5% to 11%. It is important that children are not left to play alone.

Family party also increased in fireworks injuries from 16% to 28%, while public displays and club/society displays have decreased considerably in the past 4 years. In 1998, fireworks injuries caused by family party and club/society displays had the same number of causes of injury.
